

DNS and related attacks

CSE 548 Spring 2026
jedimaestro@asu.edu

Outline

- IP and IP fragmentation basics
- Review: On-path vs. in-path vs. off-path
- Birthday attacks
 - Example: Wagner Sacramento's birthday attack on DNS (2002)
- Dan Kaminsky's DNS poisoning attack (2008) (concurrency)
- Side channel attacks (information theory)
 - Example: Fragmentation attack
- Solution: signatures
 - Important ingredient for signatures: *extended Euclidean algorithm*

Where do Internet standards come from?

- IETF = Internet Engineering Task Force
- RFC = Request for Comments
 - MUST, MUST NOT, SHOULD, SHOULD NOT, MAY (RFC 2119)
- “The only laws on the Internet are assembly and RFCs” -- Phrack 65
 - Assembly is an abstraction
 - RFCs are not always followed
 - Often ambiguous

IP reassembly

- Routers (or endhosts, if they want) can break IP packets up into fragments that the receiver has to reassemble
- Ambiguity in the way overlapping IP fragments are put back together into an IP packet
- All of the following images were plagiarized from:

<https://www.sans.org/reading-room/whitepapers/detection/ip-fragment-reassembly-scapy-33969>

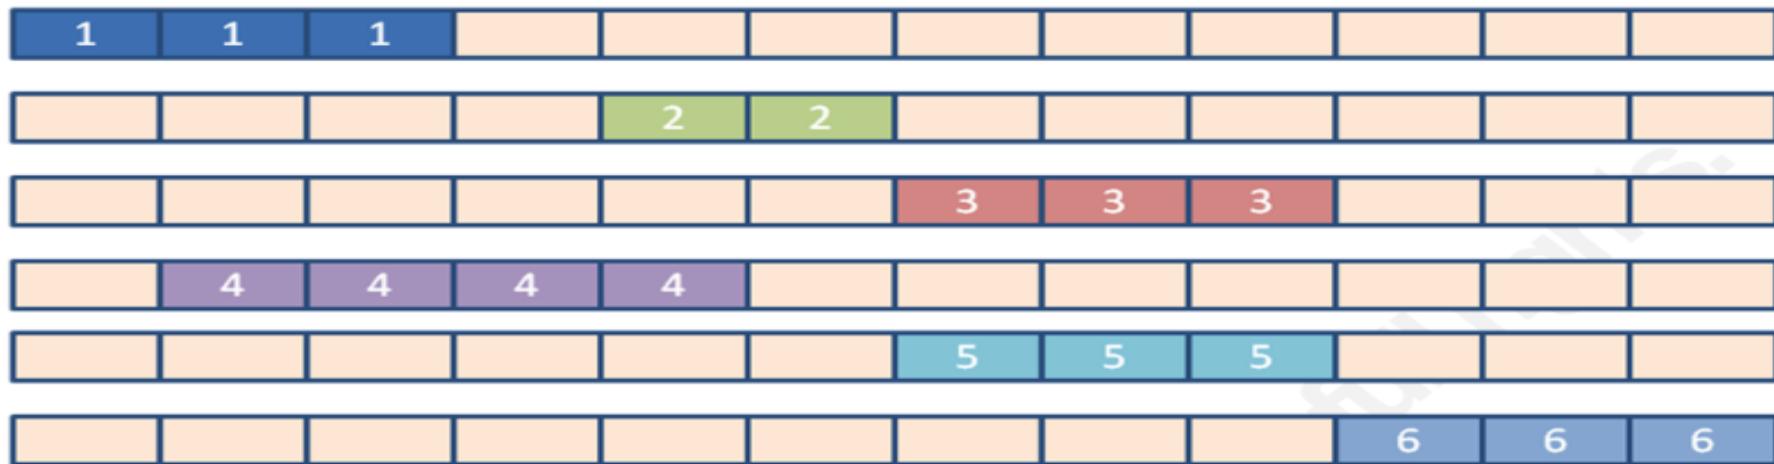

Figure 1: 6 Fragmented Packets (Shankar & Paxson, 2003)(Novak, 2005)

Reassembled using policy: First (Windows, SUN, MacOS, HPUX)

Reassembled using policy: Last/RFC791 (Cisco)

Reassembled using policy: Linux (Linux)

Reassembled using policy: BSD (AIX, FreeBSD, HPUX, VMS)

Reassembled using policy: BSD-Right (HP Jet Direct)

Figure 2: 5 Reassembly Methods (Shankar & Paxson, 2003)(Novak, 2005)

Step 1 - Attacker Crafts Linux and Windows Exploit fragments targeting a Windows host

ATTACKER VIEW

Windows Exploit
Linux Exploit

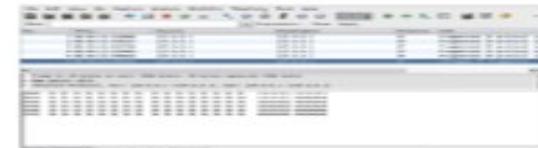

Step 2 - IDS correctly assembles packets as the target host would and alerts that the attack has occurred

IDS VIEW

Windows on Windows. successful attack ALERT!!!

Windows Exploit

Step 3 - Analyst Examines the full packet capture, sees a Linux exploit targeting Windows and dismisses the false positive

ANALYST VIEW

Linux on Windows failed attack. Stupid IDS. Next packet!!

Linux Exploit

Figure 3: Views of the attacker, IDS and analyst

judyfrags.pcap - Wireshark

What stops me from saying `www.facebook.com` is
a common name for `www.breakpointingbad.com`?

The primary goal of bailiwick checking is to prevent a malicious nameserver authoritative for example.com from providing (and a resolver from caching) records for other-example.net, or worse, for TLDs or the root zone.

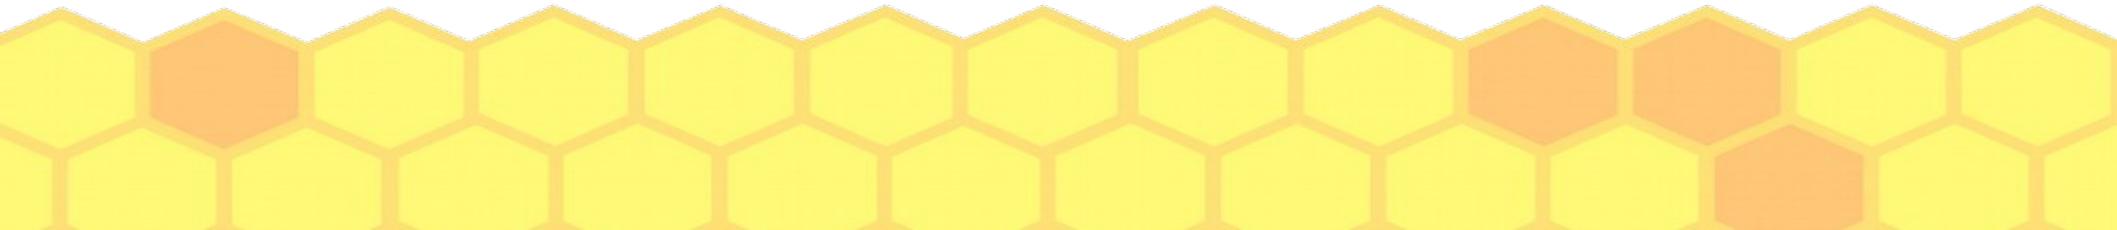

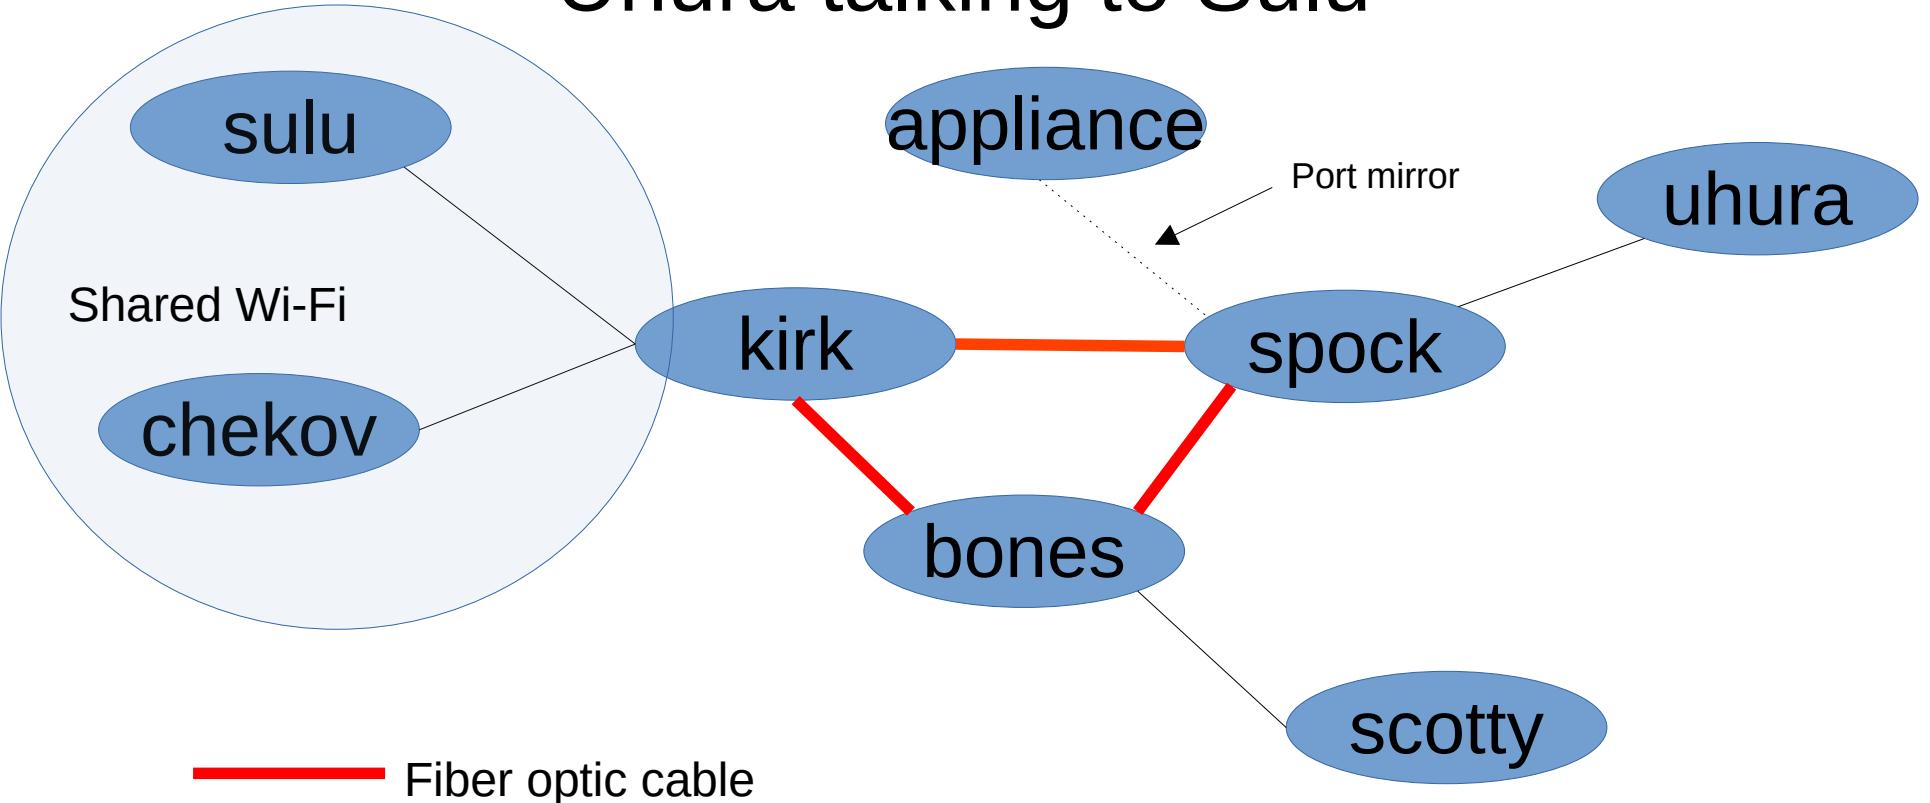

<https://datatracker.ietf.org/doc/draft-qiu-dnsop-enhanced-bailiwick/#:~:text=The%20primary%20goal%20of%20bailiwick,TLDs%20or%20the%20root%20zone>.

Introduced in the mid 90's

Uhura talking to Sulu

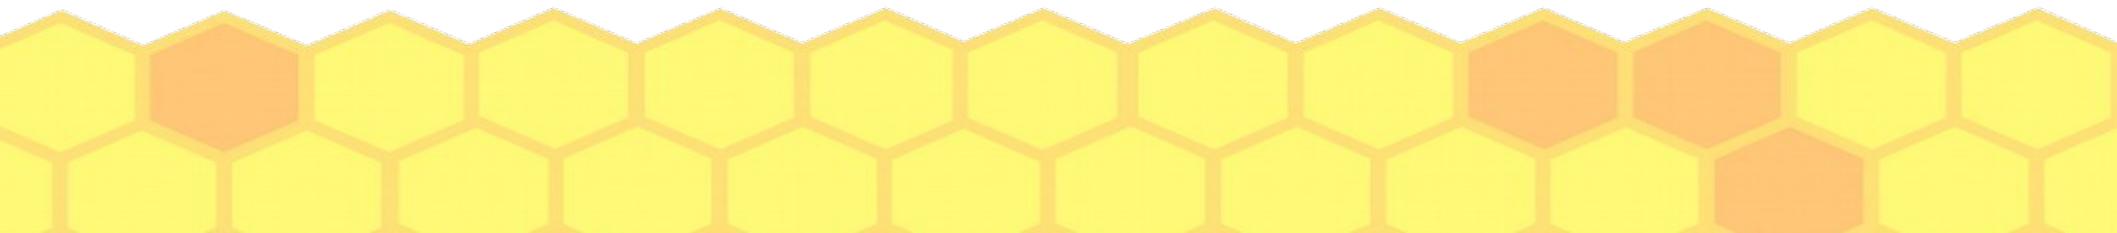

Uhura talking to Sulu

sulu == DNS client, uhura == DNS server

- kirk and spock are in-path
- appliance is on-path
 - Gets a copy of the packets from the port mirror on kirk
- chekov is on-path
 - Shared Wi-Fi with sulu, kirk has a wireless interface and two fiber optic interfaces
- scotty and bones are off-path

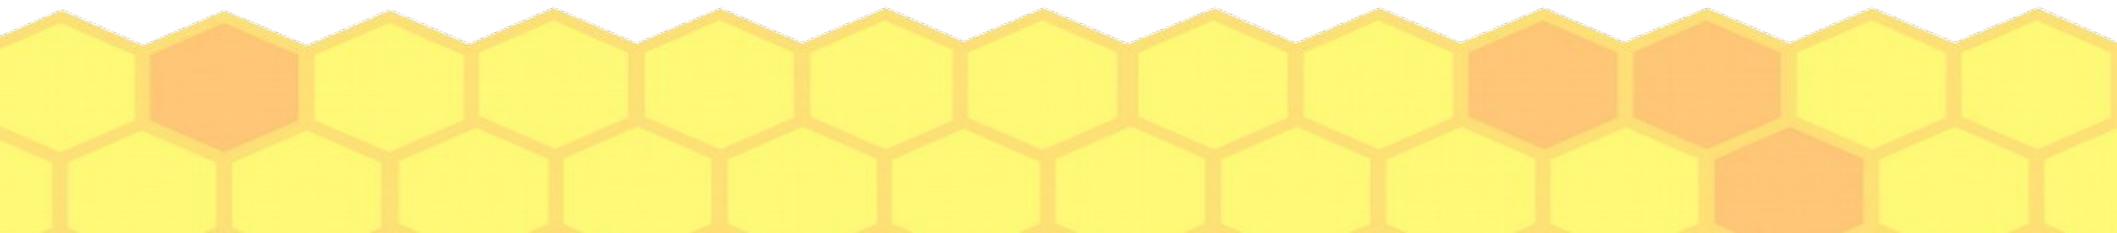

On-path attack

- Need to respond faster than the DNS server
 - Not hard, 3 seconds (example above) is an eternity
 - Maybe DoS the DNS server
- Need to get the TXID and source port correct
 - Trivial, just read them from the packet

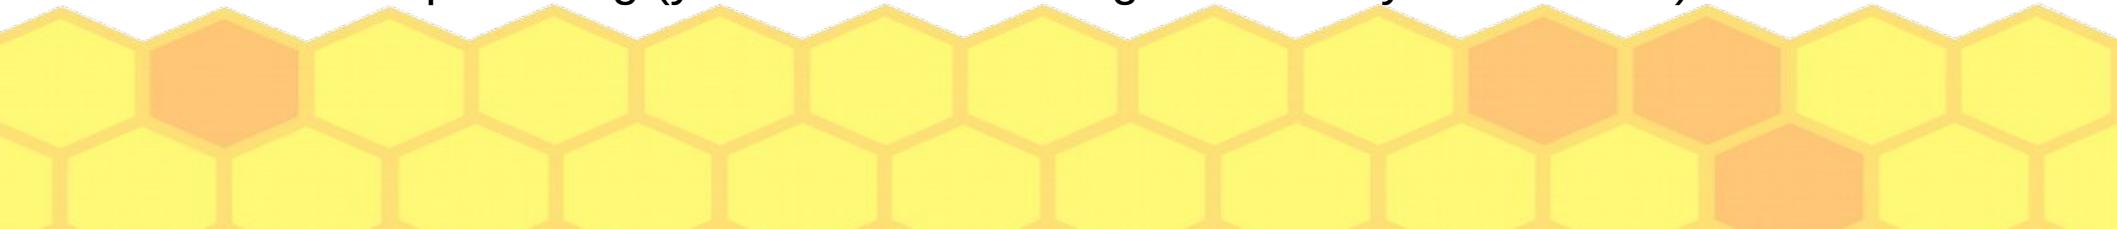

In-path attack

- ~~Need to respond faster than the DNS server~~
 - ~~Not hard, 3 seconds (example above) is an eternity~~
 - ~~Maybe DoS the DNS server~~
- Need to get the TXID and source port correct
 - Trivial, just read them from the packet
- Just don't forward the request to the DNS server
 - Or, do and then modify the response on its way back

Off-path attack

- Need to respond faster than the DNS server
 - ~~Not hard, 3 seconds (example above) is an eternity~~
 - Maybe DoS the DNS server
- Need to get the TXID and source port correct
 - **Not easy**, being off path means you're *blind* to these values
 - Guessing might work ($2^{16} * 2^{16} = 2^{32}$)
 - Side channels and birthday attacks even better
- Need to know what was queried and when
 - Cache poisoning (you know these things because you caused it)

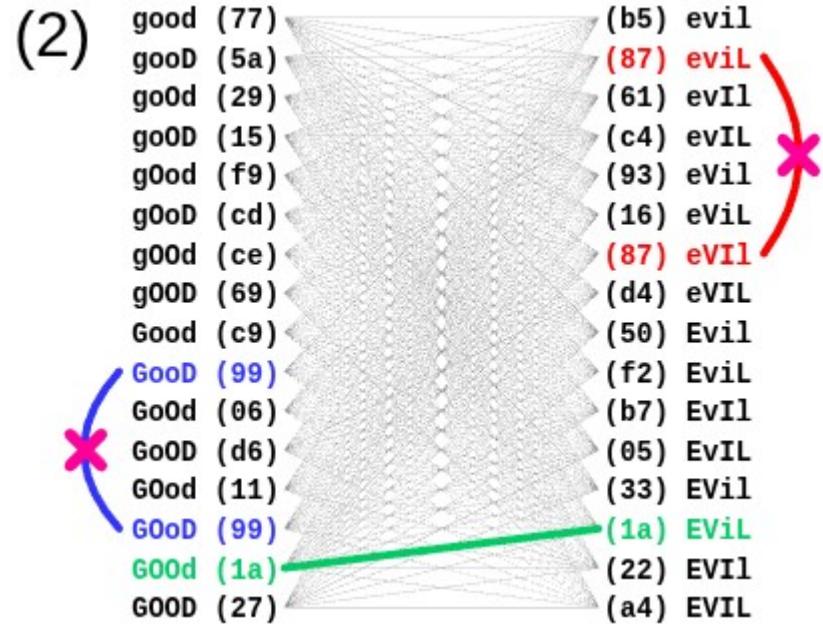

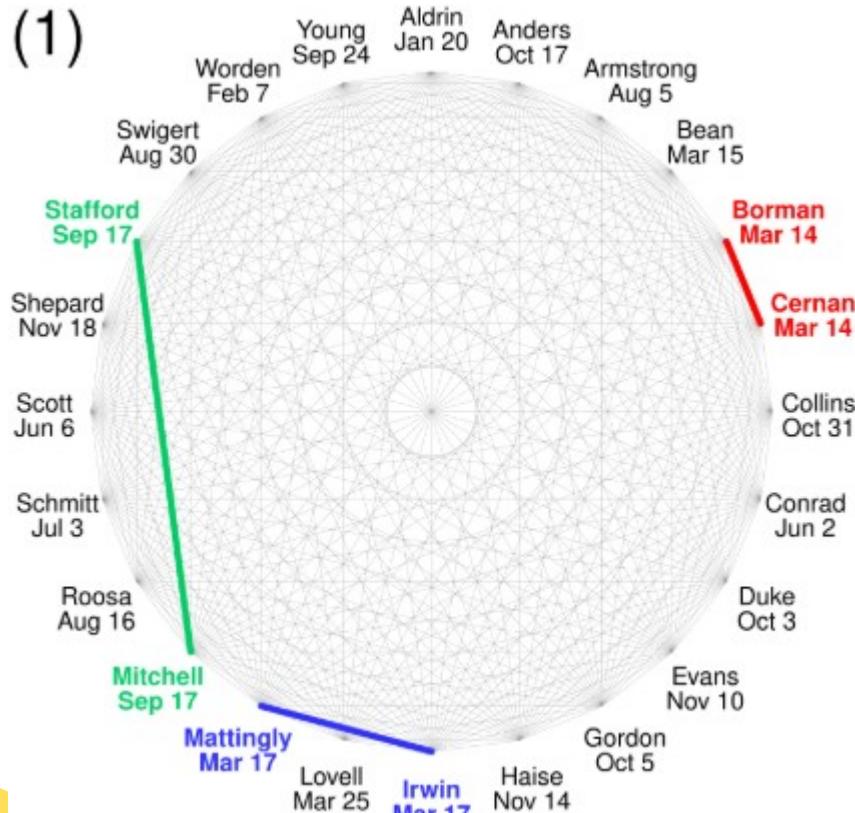

Birthday Attacks

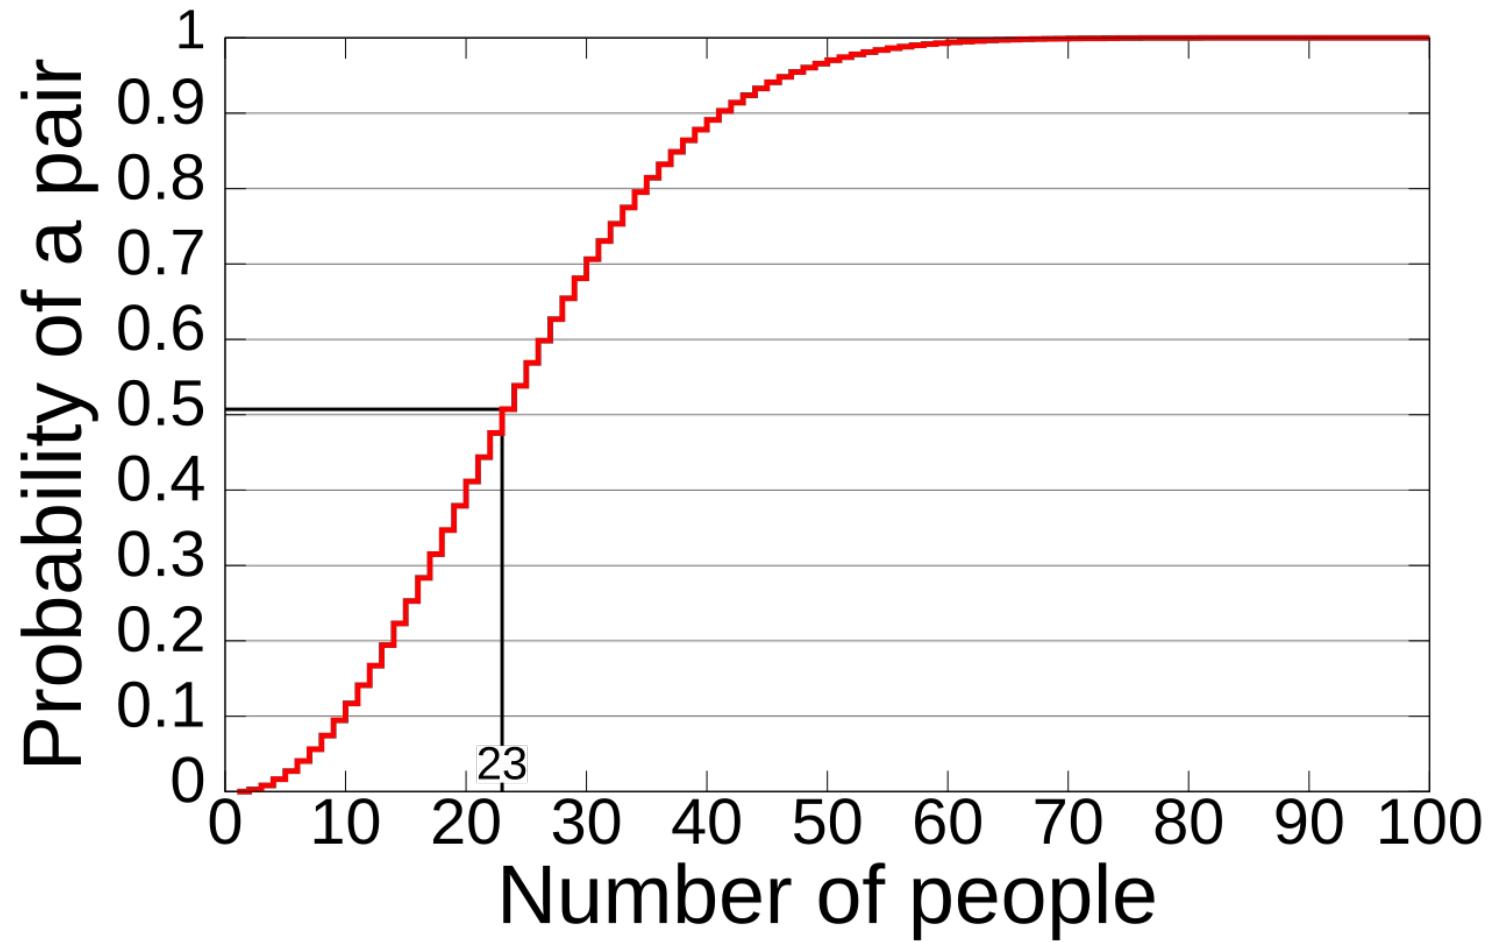

- <https://www.kb.cert.org/vuls/id/457>
- 2002

If the attacker has to guess...	...and is limited to the following number of open requests...	...it will take the following number of packets to achieve a 50% success rate (includes both requests and responses)
TID only (16bits)	1	32.7 k (2^{15})
TID only (16bits)	4	10.4 k
TID only (16bits)	200	427
TID only (16bits)	unlimited	426
TID and port (32 bits)	1	2.1 billion (2^{31})
TID and port (32 bits)	4	683 million
TID and port (32 bits)	200	15 million
TID and port (32 bits)	unlimited	109 k

Table 1: Number of packets required to reach 50% success probability for various numbers of open queries

https://en.wikipedia.org/wiki/Birthday_attack

25

Solution to the specific birthday attack on DNS
above... Don't allow multiple queries for the same
domain at the same time.

Dan Kaminsky's attack (2008)

- <https://www.blackhat.com/presentations/bh-jp-08/bh-jp-08-Kaminsky/BlackHat-Japan-08-Kaminsky-DNS08-BlackOps.pdf>

DNS is distributed

- Three possible answers to any question
 - “Here’s your answer”
 - “Go away”
 - “I don’t know, ask that guy over there”
 - This is delegation. You start with a request, and then get bounced around all over the place.
 - 13 root servers: “www.foo.com? I don’t know, go ask the com server, it’s at 1.2.3.4”
 - Com server: “www.foo.com? I don’t know, go ask the foo.com server, it’s at 2.3.4.5”
 - Foo.com server: “www.foo.com? Yeah, that’s at 3.4.5.6.”

```

- If the bad guy can reply 100 times before the good guy returns, that 65536 to 1 advantage drops to 655 to 1.
 - Alas...still long odds. And when he loses, he has to wait the TTL. That could be 655 days – almost 2 years!
 - Or maybe not.

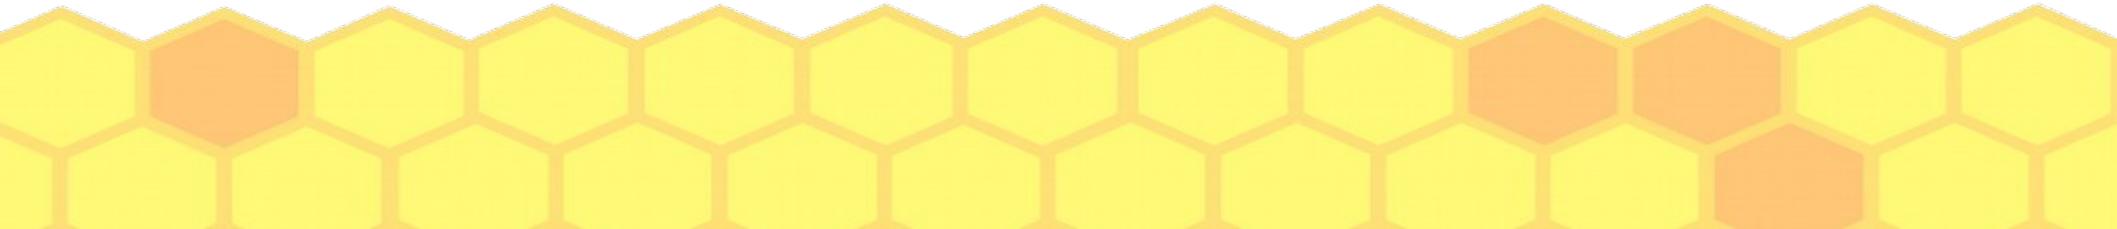

Finally, the bad guy doesn't actually need to wait to try again.

- If the bad guy asks the name server to look up www.foo.com ten times, there will only be one race with the good guy
 - The first race will be lost (most likely), and then the other nine will be suppressed by the TTL
 - No new races on this name for one more day! Here, use the answer from a while ago
 - So, can we race on other names?
- If the bad guy asks the name server to look up 1.foo.com, 2.foo.com, 3.foo.com, and so on, for ten names, there will be 10 races with the good guy
 - TTL only stops repeated races for the same name!
- Eventually, the bad guy will guess the right TXID before the good guy shows up with it
 - And now...the bad guy is the proud spoofer of ... 83.foo.com
 - So? He didn't *want* to poison 83.foo.com. He wanted www.foo.com

Bait and Switch

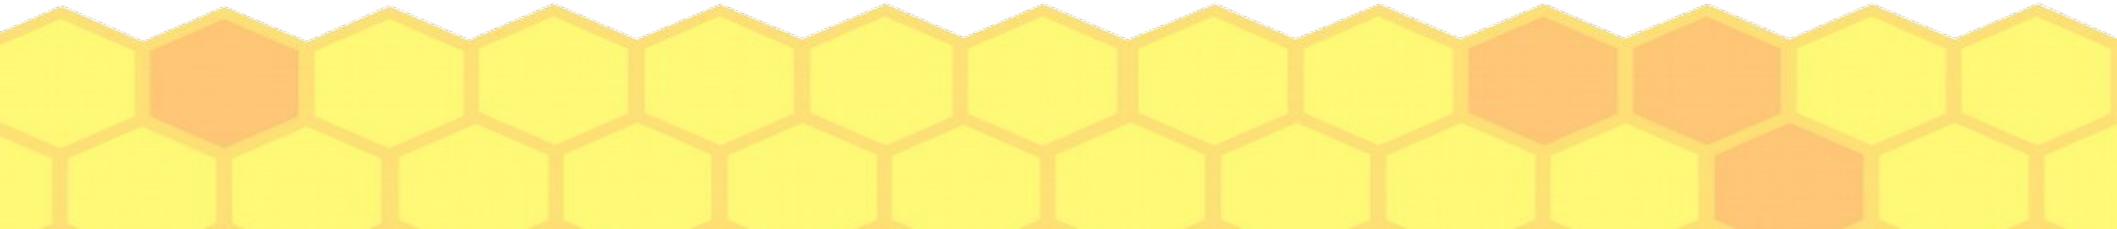

- Is it possible for a bad guy, who has won the race for 83.foo.com, to end up stealing [www.foo.com](#) as well?
 - He has three possible replies that can be associated with correctly guessed TXID
 - 1) “Here’s your answer for 83.foo.com – it’s 6.6.6.6”
 - 2) “I don’t know the answer for 83.foo.com.”
 - 3) “83.foo.com? I don’t know, go ask the [www.foo.com](#) server, it’s at 6.6.6.6”
 - This has to work – it’s just another delegation
 - 13 root servers: “83.foo.com? I don’t know, go ask the com server, it’s at 1.2.3.4”
 - Com server: “83.foo.com? I don’t know, go ask the foo.com server, it’s at 2.3.4.5”
 - Foo.com server: “83.foo.com? I don’t know, go ask the [www.foo.com](#) server, it’s at 6.6.6.6”

Does bailiwick checking save us?

Does bailiwick checking save us?

No! The only “authentication” is the source port and TXID!

Solution to the Kaminsky attack... OSes now randomize source ports.

(Also, some other stuff, like 0x20 encoding:
BrEAkPoinTiNGBaD . C0m)

But, what if we didn't have to guess the TXID or source port?

Identification (ip.id), 2 bytes

Packets: 45595 · Displayed: 2 (0.0%)

Profile: Default

IPIDs

- Used to identify fragments and put them back together
 - Should never be repeated for a given destination
- Different strategies
 - Globally incrementing counter that wraps around at 2^{16}
 - Pick at random without replacement
 - Per-destination
 - Bucket-based
 - Can add noise

How much entropy?

- Globally incrementing counter?
- Pick at random?

FROM THE MAKERS OF WOLFRAM LANGUAGE AND MATHEMATICA

$$65535 * \left(\frac{1}{65535} \right) \log_2 \left(\frac{1}{65535} \right)$$

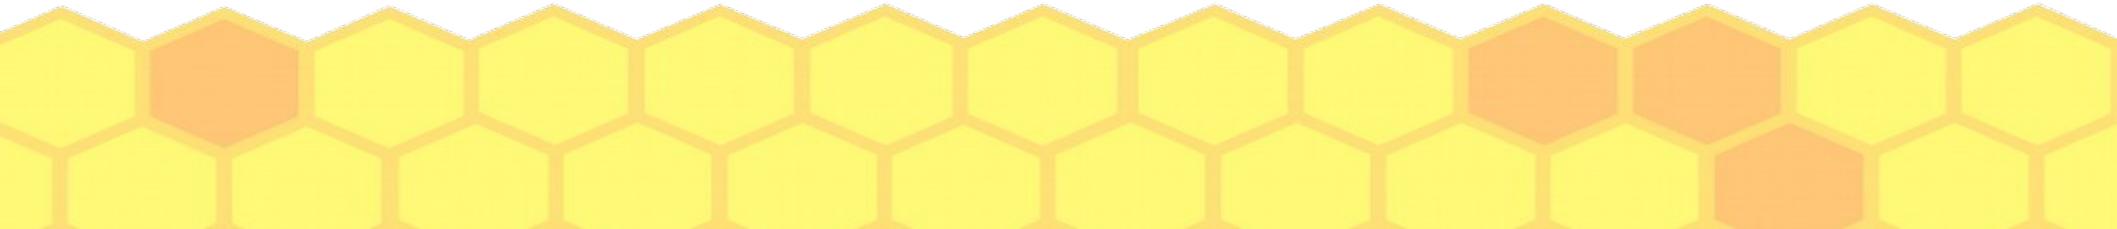

15.9999779860527360444979834869216776403570...

47

How much entropy?

- Per-destination?
 - Think about a noisy server that is talking to other clients
- Bucket-based?

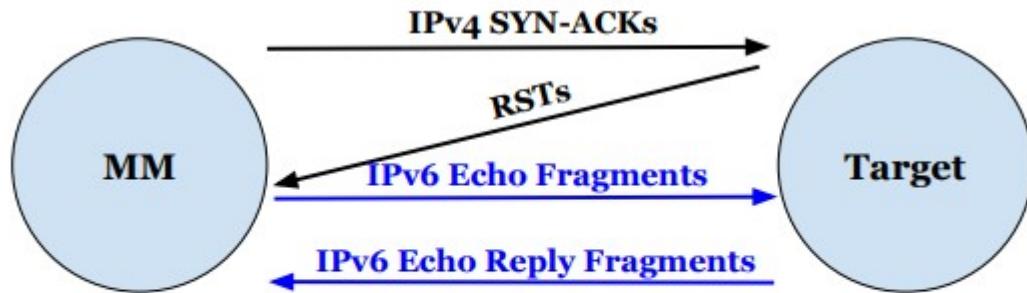

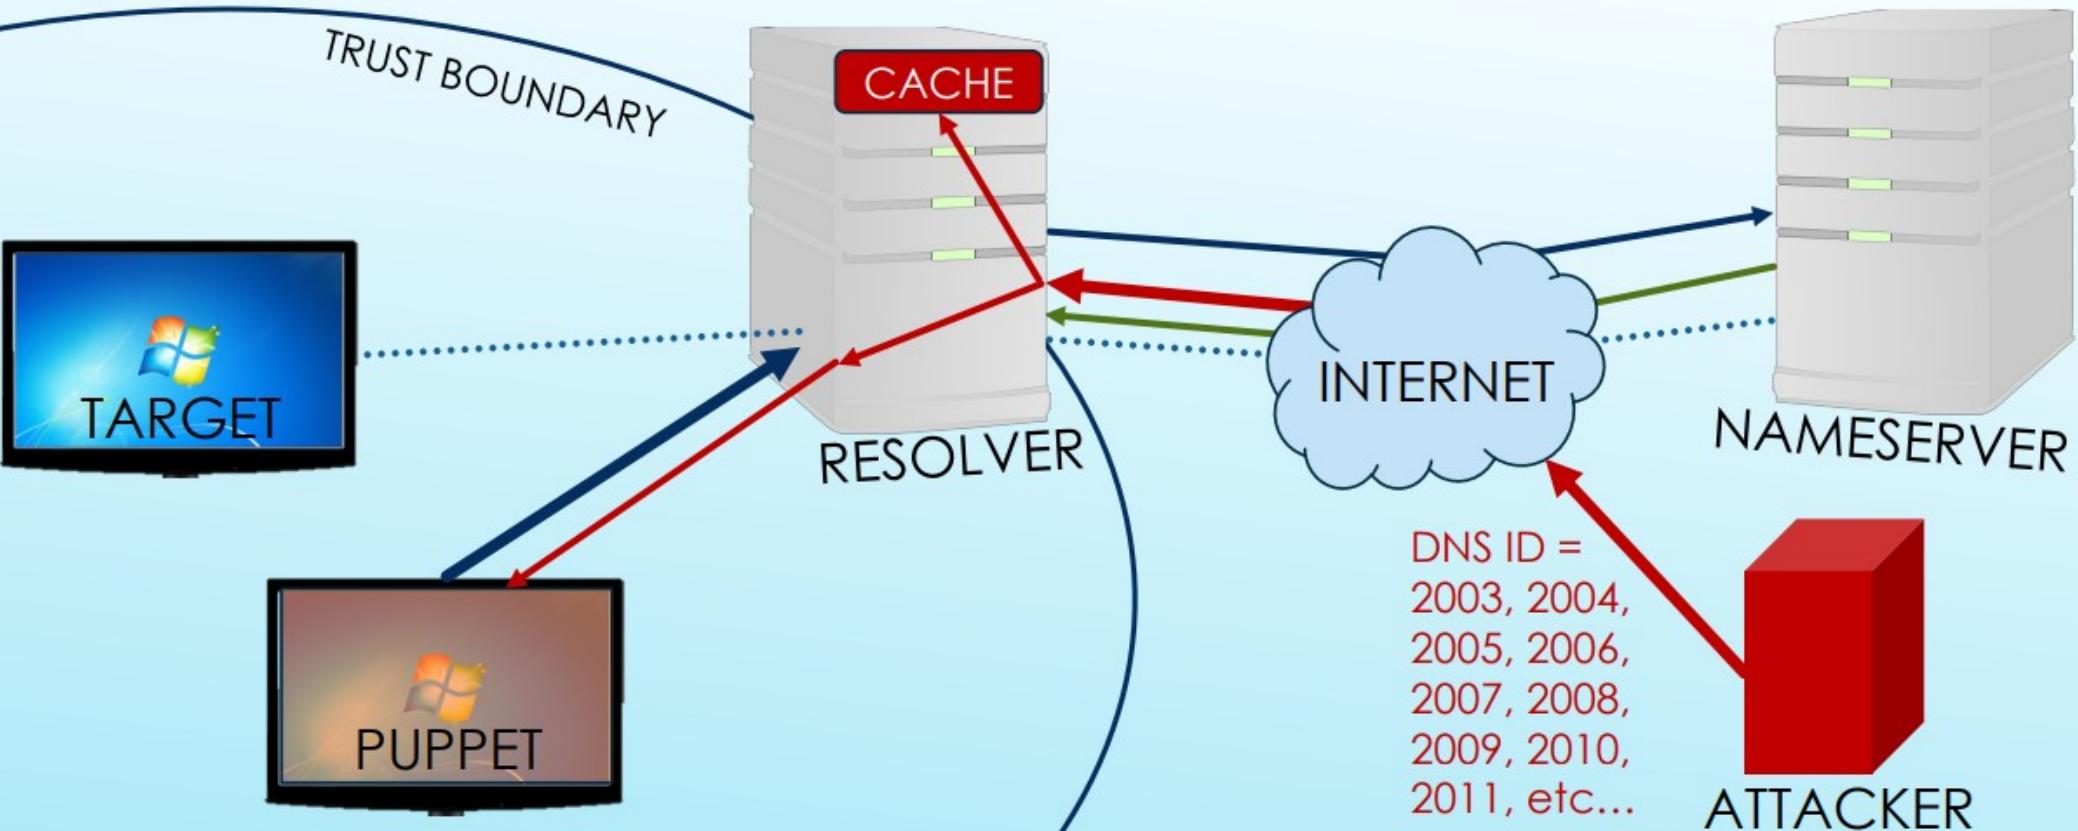

Fig. 3. IPv4 and IPv6 alias resolution.

Fragmentation attacks on Linux resolvers

- <https://media.defcon.org/DEF%20CON%202027/DEF%20CON%2027%20presentations/DEFCON-27-Travis-Palmer-First-try-DNS-Cache-Poisoning-with-IPv4-and-IPv6-Fragmentation.pdf>

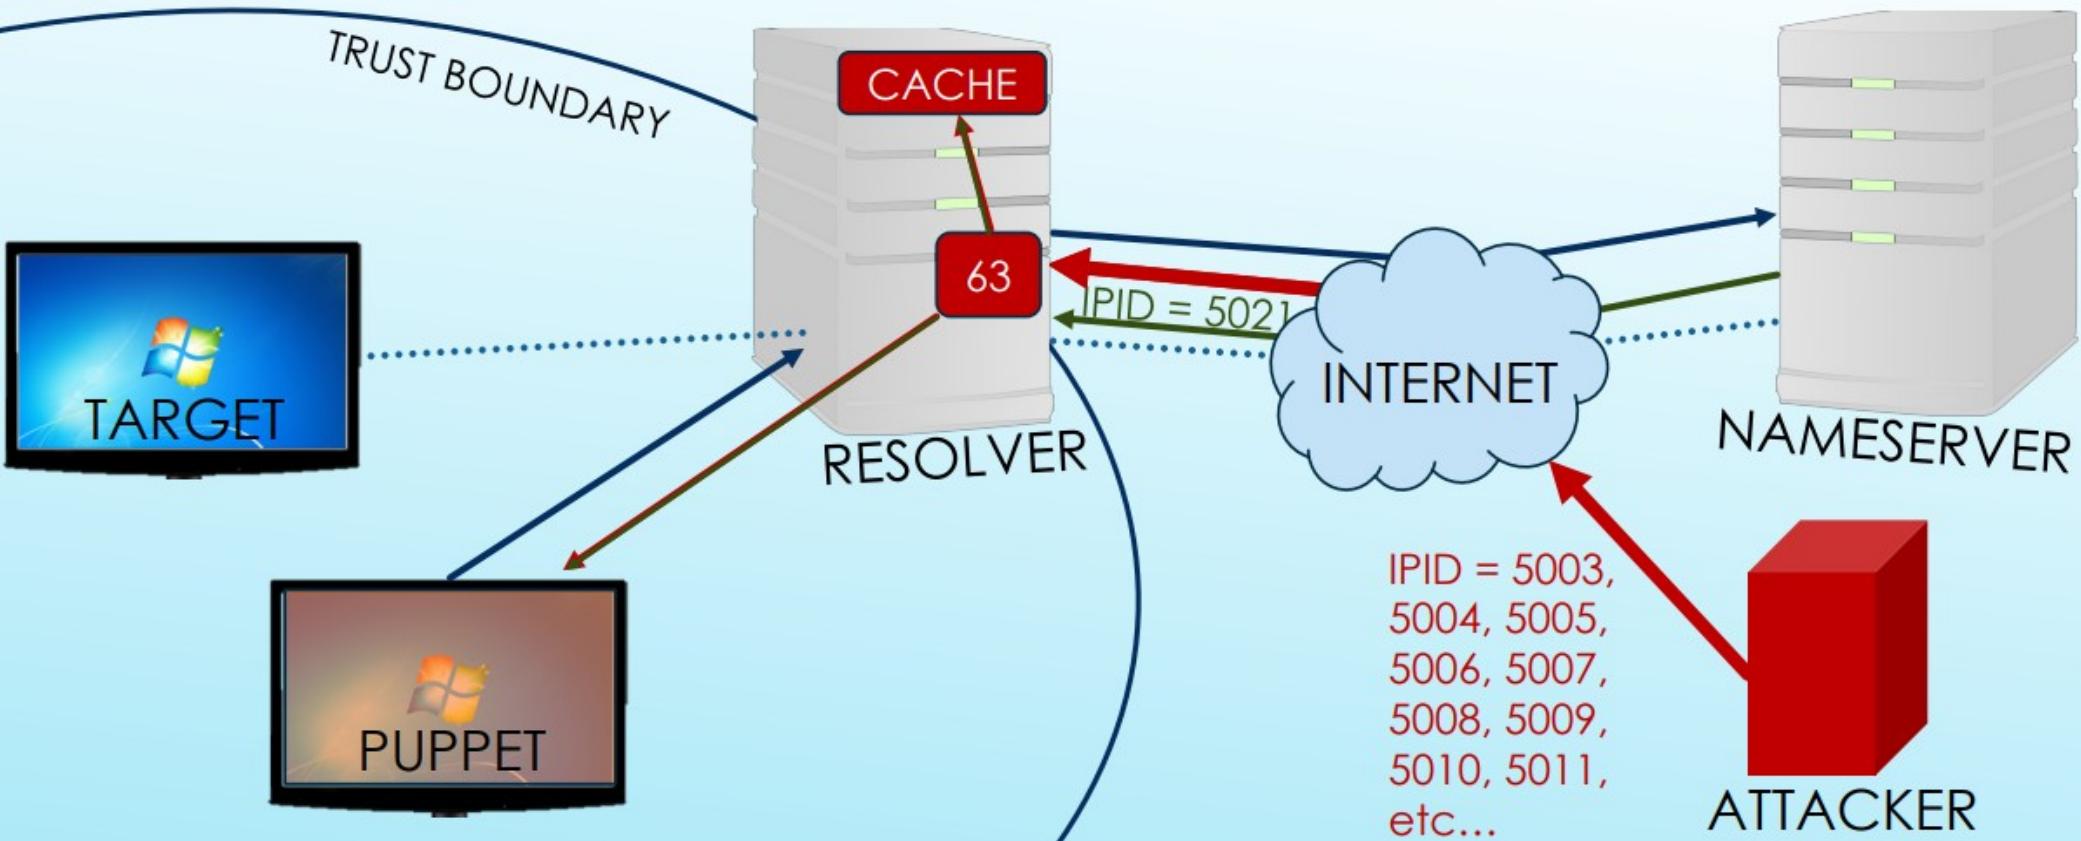

Kaminsky's attack, assuming source port is completely predictable and you only need to guess the TXID...

IDEAL POISONING SCENARIO

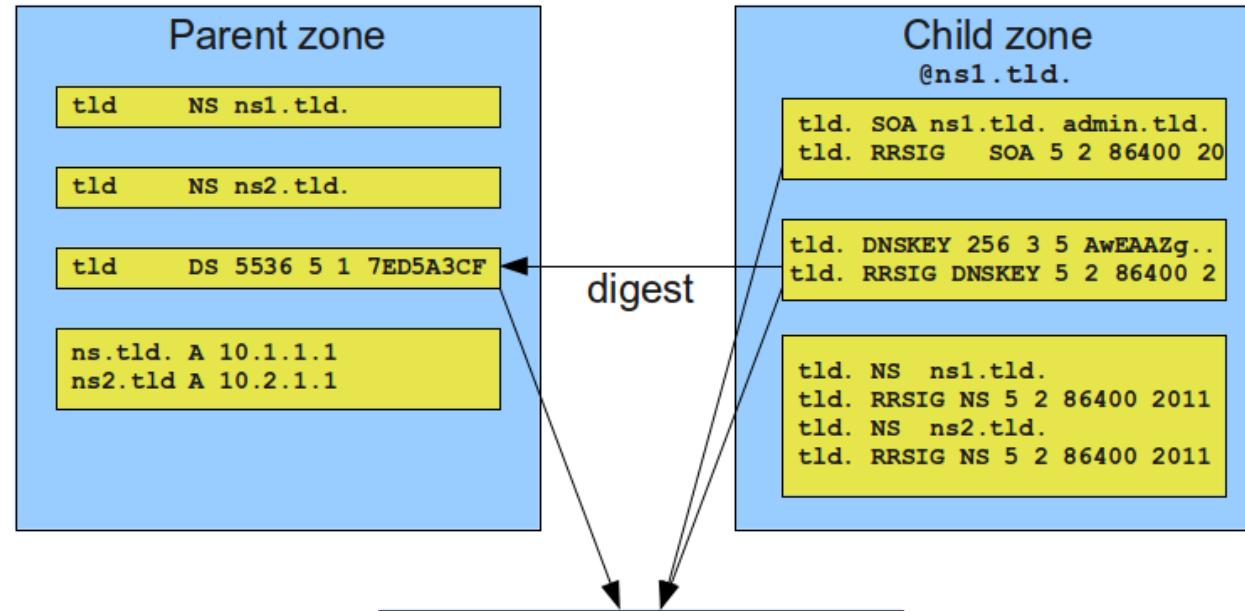

Fragmentation attacks, only need to guess IPID
(TXID and source port are in existing fragment
from the DNS server)...

IDEAL POISONING SCENARIO

A real solution would be a real form of authentication, like signatures...

DNSSEC
